ANOVA I. Decomposition of Variance

Miaoyan Wang

Department of Statistics UW Madison

Reading: Chapter 4 in R.C. Chapter. 13-14 in J.F.

ANOVA Approach to Regression Analysis

The idea is to partition the variation into

$$SS Total = SS Model + SS Error$$

- Why partition the variation?
 - Weigh different sources of variation.
 - Hypothesis testing.
- In the linear regression, consider three types of partitions.
 - Deviation for each observation.
 - Total sum of squares.
 - Degrees of freedom.

Partitioning Deviation of Each Observation

$$\underline{Y_i - \bar{Y}} = \hat{\underline{Y}_i - \bar{Y}} + \underline{Y_i - \hat{Y}_i}$$

total dev of fitted from mean dev of obs from fitted

• If $\{\hat{Y}_i - \bar{Y}\}$ are large in relation to $\{Y_i - \hat{Y}_i\}$: then the regression relation explains a large proportion of the total variation in $\{Y_i\}$.

Partitioning Total Sum of Squares

$$\underbrace{\sum_{i=1}^{n} (Y_i - \bar{Y})^2}_{\text{SSTO}} = \underbrace{\sum_{i=1}^{n} (\hat{Y}_i - \bar{Y})^2}_{\text{SSR}} + \underbrace{\sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2}_{\text{SSE}}.$$

• The total sum of squares (SSTO) is

SSTO =
$$\sum_{i=1}^{n} (Y_i - \bar{Y})^2 = \sum_{i=1}^{n} Y_i^2 - \frac{1}{n} \left(\sum_{i=1}^{n} Y_i \right)^2$$

A measure of total variation in the data (compare to variance).

Partitioning Total Sum of Squares

$$\sum_{i=1}^{n} (Y_{i} - \bar{Y})^{2} = \sum_{i=1}^{n} (\hat{Y}_{i} - \bar{Y})^{2} + \sum_{i=1}^{n} (Y_{i} - \hat{Y}_{i})^{2}.$$
SSR

• The regression sum of squares (SSR) is

SSR =
$$\sum_{i=1}^{n} (\hat{Y}_{i} - \bar{Y})^{2}$$
, where $\hat{Y} = \hat{\beta}_{0} + \hat{\beta}_{1}X_{1} + \ldots + \hat{\beta}_{p}X_{p}$

The larger the SSR in relation to SSTO, the larger the proportion of variability in the Y_i 's accounted for by the regression relation.

Partitioning Total Sum of Squares

$$\underbrace{\sum_{i=1}^{n} (Y_i - \bar{Y})^2}_{\mathsf{SSTO}} = \underbrace{\sum_{i=1}^{n} (\hat{Y}_i - \bar{Y})^2}_{\mathsf{SSR}} + \underbrace{\sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2}_{\mathsf{SSE}}.$$

• The error sum of squares (SSE) is

$$SSE = \sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2 = SSTO - SSR$$

The greater the variation of the Y_i 's around the fitted regression line, the larger the SSE.

Sums of Squares

 Following arguments for SLR in matrix terms, we have sums of squares

SSR =
$$\sum_{i=1}^{n} (\hat{Y}_i - \bar{Y})^2 = \mathbf{Y}'(\mathbf{H} - \frac{1}{n}\mathbf{J})\mathbf{Y}$$
SSE =
$$\sum_{i=1}^{n} (Y_i - \hat{Y}_i)^2 = \mathbf{Y}'(\mathbf{I} - \mathbf{H})\mathbf{Y}$$
SSTO =
$$\sum_{i=1}^{n} (Y_i - \bar{Y})^2 = \mathbf{Y}'\left(\mathbf{I} - \frac{1}{n}\mathbf{J}\right)\mathbf{Y}$$

Partitioning of total sum of squares and the corresponding df are

$$\underbrace{\mathsf{SSTO}}_{df=n-1} = \underbrace{\mathsf{SSR}}_{df=p-1} + \underbrace{\mathsf{SSE}}_{df=n-p}.$$

Coefficient of Multiple Determination

• The **coefficient of multiple determination** is denoted by R^2 and is defined as

$$R^2 = \frac{\mathsf{SSR}}{\mathsf{SSTO}} = 1 - \frac{\mathsf{SSE}}{\mathsf{SSTO}}$$

• Interpretation: The proportion of variation in the Y_i 's "explained" by the regression relation.

Adjusted Coefficient of Multiple Determination

- What is effect of more explanatory variables on R^2 ?
- The adjusted coefficient of multiple determination is denoted by R_a^2 and is defined as

$$R_a^2 = 1 - \frac{\frac{\text{SSE}}{n-p}}{\frac{\text{SSTO}}{n-1}} = 1 - \left(\frac{n-1}{n-p}\right) \frac{\text{SSE}}{\text{SSTO}}.$$

• Interpretation:

The adjusted coefficient of multiple determination R_a^2 may decrease when more explanatory variables are in the model.

Summary: ANOVA table

The ANOVA table is

Source	df	SS	MS	F
Regression	p - 1	SSR	MSR	F = MSR/MSE
Error	n-p	SSE	MSE	_
Total	n – 1	SSTO	_	_

What are the last two columns?

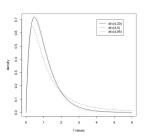

Preparation: Definition of F

F-distribution

An F random variable with ν_1 numerator degrees of freedom and ν_2 denominator degrees of freedom is

$$F_{\nu_1,\nu_2} = \frac{\chi_{\nu_1}^2/\nu_1}{\chi_{\nu_2}^2/\nu_2}$$

where $\chi^2_{\nu_1}$ and $\chi^2_{\nu_2}$ are independent. In particular, $\chi^2_{\nu}\nu=F_{\nu,0}.$

Preparation: Cochran's Theorem

Cochran's Theorem

Consider a linear regression model where SSTO is decomposed into k terms of SS_r, each with degrees of freedom df_r, where $\sum_{r=1}^k \mathrm{df}_r = n-1$. Then under the null $H_0: \beta_1 = \ldots = \beta_k = 0$,

$$SS_r/\sigma^2 \sim \chi^2_{df_r}$$
, independent w.r.t. $r=1,\ldots,k$.

Expectation of quadratic forms

Suppose $\mathbf{Y} \sim \mathcal{MVN}(\mu, \mathbf{\Sigma})$, and \mathbf{M} is a symmetric matrix of constants. Then, $\mathbb{E}(\mathbf{Y}^T \mathbf{MY}) = \operatorname{tr}(\mathbf{M\Sigma}) + \boldsymbol{\mu}^T \mathbf{M} \boldsymbol{\mu}$.

Mean Squares

• Define mean squares

$$MSR = \frac{SSR}{p-1}, \quad MSE = \frac{SSE}{n-p}.$$

• From Cochran's Theorem, we prove that

$$\mathbb{E}(\mathsf{MSE}) = \sigma^2.$$

Proof:

$$\mathbb{E}(\mathsf{SSE}) = (\boldsymbol{X}\boldsymbol{\beta})'(\boldsymbol{I} - \boldsymbol{H})(\boldsymbol{X}\boldsymbol{\beta}) + \mathsf{tr}(\sigma^2(\boldsymbol{I} - \boldsymbol{H}))$$
$$= 0 + (n - p)\sigma^2$$

• Thus, we estimate σ^2 by

$$\hat{\sigma}^2 = MSE.$$

Mean Squares

Define mean squares

$$MSR = \frac{SSR}{p-1}, \quad MSE = \frac{SSE}{n-p}.$$

Similar calculatin shows that

$$\mathbb{E}(\mathsf{MSR}) \quad \left\{ \begin{array}{l} = \sigma^2 : & \mathsf{if} \ \beta_1 = \dots = \beta_{p-1} = 0; \\ > \sigma^2 : & \mathsf{otherwise} \end{array} \right.$$

Proof.

$$\mathbb{E}(\mathsf{SSR}) = (\boldsymbol{X}\beta)' \left(\boldsymbol{H} - \frac{1}{n}\boldsymbol{J}\right) (\boldsymbol{X}\beta) + \operatorname{tr}(\sigma^2(\boldsymbol{H} - \frac{1}{n}\boldsymbol{J}))$$

$$= \sum_{i=1}^n \{\beta_1(X_{i1} - \bar{X}_1) + \ldots + \beta_{p-1}(X_{i,p-1} - \bar{X}_{p-1})\}^2 + (p-1)\sigma^2$$

Summary: ANOVA table

The ANOVA table is

Source	df	SS	MS	F
Regression	<i>p</i> – 1	SSR	MSR	F = MSR/MSE
Error	n-p	SSE	MSE	_
Total	n-1	SSTO	_	_

What is the last column?

Linear Regression and ANOVA

Consider the full model (or, unrestricted model)

$$Y_i = \beta_0 + \beta_1 X_i^1 + \dots + \beta_{p-1} X_i^{p-1} + \varepsilon_i, \quad \varepsilon_i \sim \text{iid } N(0, \sigma^2)$$
 and obtain SSE(F).

• Consider the **reduced model** (or, **restricted model**) under the $H_0: \beta_1 = \beta_2 = \ldots = \beta_{p-1} = 0$

$$Y_i = \beta_0 + \varepsilon_i, \quad \varepsilon_i \sim \text{iid } N(0, \sigma^2)$$

and obtain SSE(R).

• It can be shown that $SSE(F) \leq SSE(R)$.

Overall F Test for Regression Relation

Test

$$H_0: \beta_1 = \cdots = \beta_{p-1} = 0$$

 H_A : otherwise, i.e, at least one of the coefficients is non-zero

• Under the H_0 : $\beta_1 = \ldots = \beta_{p-1} = 0$,

$$F^* = \frac{MSR}{MSE} = \frac{\frac{SSE(R) - SSE(F)}{df_R - df_F}}{\frac{SSE(F)}{df_F}} \sim F_{df_R - df_F, df_F}$$

- Thus we can perform an F-test at level α by the decision rule: If the observed test statistic $f^* > f_{p-1,n-p,\alpha}$, reject H_0 . Otherwise, do not reject H_0 .
- Continue to use p-value to gauge the strength of evidence against the H_0 .
- Suppose H_0 is rejected, we may further look into which β 's are significantly different from 0.

Example: Wetland Species Richness

• For the wetland species richness example,

Source	df	SS	MS	F	p-value
Forest cover	1	49.82	49.817	5.824	0.0191
Error	56	479.03	8.554	_	_
Total	57	528.85	_	_	_

• To test $H_0: \beta_1 = 0$ vs $H_A: \beta_1 \neq 0$, the observed F test statistic is

$$f^* = \frac{49.817}{8.554} = 5.824$$

• Compared with $F_{1,56}$, the p-value is

$$P(F_{1,56} > 5.824) = 0.0191.$$

The coefficient of determination is

$$R^2 = \frac{49.82}{528.85} = 0.0942$$

• Interpretation:

Remarks on R^2

Misunderstandings

- ► A high R² indicates that accurate predictions can be made. not necessary. there may still lack precision in prediction.
- ► A high R² indicates that the estimated regression line is a good fit. not necessary. will see in goodness of fit test
- ► An R² near zero indicates that X and Y are not related. not necessary. small but significant linear coefficient; curvilinear relationship.

Remarks

- ▶ SSR is "explained variation" and SSE is "unexplained variation" in *Y*. However, *Y* does not necessarily depend on *X* in a causal sense.
- ► SLR model does not contain a population parameter for which R² estimates.
- ▶ When X are more spread out, R^2 tends to be higher.
